

Transit Supply Index scores on the days of the  
2016 and 2021 censuses: using Statistical Area  
Level 1 (SA1) 2016 boundaries

James Reynolds and Graham Currie

2023-08-22

# *Introduction*

Previous research by Currie and Senbergs [2007] developed a transit Supply Index (SI), based on calculating the number of transit arrivals at stops within an area of interest, adjusted to account for the typical walk-access catchment for each stop. The Public Transport Research Group (PTRG) has been developing R code to calculate this Supply Index directly from GTFS data. This document describes how the code has been used to output SI scores for the day of the 2016 census and the day of the 2021 census for each of the Australian Bureau of Statistics (ABS) 2016 Statistical Area Level 1 (SA1) zones in Victoria<sup>1</sup>. It also presents verification checks to determine the accuracy of the output scores, and shows some statistical analysis of the scores as a way of exploring the output.

This rest of this document is structured as follows: the next section discusses the research context of the Supply Index. In the third section the methodology for the code development is outlined, including discussion of the case study GTFS for Victoria, Australia, that was used to test and verify the code output. In the fourth section results are presented, starting with verification of the code output through hand-calculation of SI scores for Statistical Area 1 (SA1) areas in the Victorian Alps and Talbot. SI scores for SA1s across the Clayton Statistical Area Level 2 (SA2) zone and the Melbourne City Statistical Area Level 3 (SA3) zones are also examined, followed by a review of the SI scores for SA1s across all of Greater Melbourne and all of Victoria. Mode-by-mode SI scores are also explored, followed by an examination of needs-gaps across the ABS Index for Relative Socio-Economic Advantage/Disadvantage (IRSAD) scores, ranks and population levels. The document then closes with a brief discussion and conclusion section.

<sup>1</sup> These scores have been requested by Maryam Jafari as an input to her PhD project.

# Research context

## The Supply Index

Equation 1<sup>2</sup> shows the Supply Index<sup>3</sup>. An advantage of the Supply Index is that it is a relatively simple number to calculate, understand and explain. It describes the number of transit arrivals at stops within an area of interest and time frame, multiplied by a factor accounting for the proportion of the area of interest that is within typical walking distance of each stop. Hence, more services, more stops and higher frequencies would all result in an increase in Supply Index score.

The Supply Index does not incorporate further aspects, such as service span, off-peak share of service or service speed, which are a feature of the Transit Capacity and Quality of Service Manual (TC-QSM) [Kittleson & Associates et al., 2013] and other transit supply metrics. However, including such factors may increase the complexity of calculating and describing the index to non-transit specialists.

Simplicity is also helped by the way that the SI is additive. Hence,  $SI_{area,time}$  scores can be aggregated to calculate an overall score across multiple time periods or for a region encompassing multiple areas of interest.

Currie and Senbergs [2007] calculated the  $SI_{area,time}$  for various Census Collection Districts (CCDs)<sup>4</sup> in Melbourne using a timetable database provided by the Victorian Public Transport Authority (PTA). This predated the widespread availability of GTFS data. A question, therefore, is how to calculate the SI using GTFS data so that  $SI_{area,time}$  scores can be calculated and compared for any area of interest where transit service information is available in that format.

## Transport Needs Index(es)

Currie and Senbergs [2007] also developed a Transport Needs Index based around population, transport and employment data. This was combined with the ABS' Index for Relative Socio-Economic Advantage/Disadvantage (IRSAD) to produce a combined index addressing social and transport needs. This was then used to assess the gap be-

$$SI_{area,time} = \sum \frac{Area_{Bn}}{Area_{area}} * SL_{n,time} \quad (1)$$

<sup>2</sup> In Equation 1  $SI_{area,time}$  is the Supply Index for the area of interest and a given period of time.  $Area_{Bn}$  is the buffer area for each stop (n) within the area of interest. In Currie and Senbergs [2007] this was based on a radius of 400 metres for bus and tram stops, and 800 metres for railway stations.  $Area_{area}$  is the area of the area of interest, and  $SL_{n,time}$  is the number of transit arrivals for each stop for a given time period.

<sup>3</sup> Minor adjustments have been made to generalise the equation, as Currie and Senbergs [2007] focused on the context of Melbourne's Census Collection Districts (CCD) and calculations based on a week of transit service.

<sup>4</sup> CCDs predate the introduction of Statistical Areas 1, 2, 3, and 4 (SA1, SA2, SA3, SA4), and other geographical divisions currently used by the Australian Bureau of Statistics (ABS), which may be more familiar to readers.

tween transit needs and supply.

Later in this document a similar needs-gap analysis is presented for Victorian SA1s. However, in the needs-gap analysis here only the IRSAD scores and population data are reported. Calculating the combined Transport Needs index as per Currie and Senbergs [2007] may be a direction for future research.

# Methodology

This document has been prepared using Rmarkdown, which allows the intermingling of written text, code segments and code outputs. Code segments developed in this research are shown in the following, together with the relevant descriptive text<sup>5</sup>. This specific document is part of a branch of the developed code, specifically created for reporting the calculation of the SI scores for the SA12016 zones.

Various analysis tools are available that make use of GTFS data, including the tidytransit package [Poletti et al., 2023] for the R statistical programming language [R Core Team, 2023]. Poletti [undated] provides code to calculate a departure timetable from a GTFS feed, and this was adapted to calculate arrivals at a stop and the  $SL_{Bn}$  term in the Currie and Senbergs [2007] SI equation.

The gtfstools R package [Herszenhut et al., 2022] was used to split input GTFS feeds by mode to facilitate the buffer zone calculation. Buffer zones of 400 metres for bus and Light Rail Transit (LRT) services and 800 metres for heavy rail were adopted, as per Currie and Senbergs [2007]<sup>6</sup>.

Where transit stops are located close to boundaries their catchment areas may fall into multiple areas of interest. The sp package [Pebesma, 2023] provides tools for manipulating geographic data and shape files in R. This was used to calculate the proportion of each stop's catchment area that falls into each geographical area of interest<sup>7</sup>.

The  $SI_{area}$  term in the SI equation was calculated on a mode-by-mode and stop-by-stop basis, by first determining the amount of the catchment area ( $Area_{Bn}$ ) that falls into each geographical area of interest for the stop in question. This is then combined with the area for each geographical area of interest ( $Area_{area}$ ) and the number of stop arrivals ( $SL_{Bn}$ ) to calculate the contribution to the SI scores made by just that single stop for every area of interest. These are then added to a cumulative total field for each area of interest, and the calculations are repeated until all stops and modes in the GTFS file have been included.

<sup>5</sup> The Rmarkdown file is available at [https://github.com/James-Reynolds/Transit\\_Supply\\_Index\\_GTFS/tree/SA12016\\_analysis](https://github.com/James-Reynolds/Transit_Supply_Index_GTFS/tree/SA12016_analysis) and this can be read in a plain-text editor to view the code snippets themselves. If you are reading this in a PDF document you are seeing just the descriptive text, and outputs from the code where it has been run to produce maps, charts etc.

<sup>6</sup> There is an extended mode definition that includes modes beyond the 10 in the GTFS standard [Herszenhut et al., undated], but these are not dealt with by the gtfstools package. Further research may seek to extend this such that other modes can be included, but for the purposes of this study the coded buffer zone was set at 400 metres for cable trams, aerial lifts such as gondolas and trolleybuses, and at 800 metres for ferries, funiculars and monorails.

<sup>7</sup> GTFS files define stop locations based on latitude and longitude [MobilityData, undated], whereas the  $Area_{Bn}$  calculation needs to be provided in the same units as the  $Area_{area}$  variable, necessitating the use of a geographic transform as part of the code.

### *Case research approach*

To test the developed code and output results analysis was generated for SA1 zones within two case study areas: Clayton (SA2) and Melbourne City (SA3). Results were processed using the ggmaps [Kahle et al., 2023], ggplot [Wickham et al., 2023], ggstatsplot [Patil, 2023] and kable [Zhu, 2021, Xie, 2023] packages, with data processing leveraging the tidyverse approach [Wickham, 2023].

### *Victoria, Australia*

Victoria is the southern-most state on the Australian mainland. The state capital is in Melbourne, which has a similar metropolitan area to of Paris or London<sup>8</sup>. However, with only around 5 million people Melbourne has about one-third of the population density. It has an inner Central Business District (CBD) with apartments, commercial skyscrapers and extensive sporting facilities nearby; surrounded by low-density, predominately single-family-housing-dominated, inner, middle and outer suburbs.

There are train and tram networks radiating from the CBD, but for most of the suburban areas the reality is that transit is provided by circuitious bus routes that are mostly used by those who cannot otherwise drive. An extensive freeway (and tollway) network provides connections across the Greater Melbourne area, further around Port Phillip Bay to Geelong (south-west) and the Mornington Peninsula (south-east) as well as to regional centres elsewhere in Victoria. There is a state-wide regional train and bus network (VLine), which also provides connections into South Australia, New South Wales and the Australian Capital Territory (Canberra) and local bus services in many regional towns and cities. However, accessibility to most of the city and state tends to be car-dominated. The Overland train service to Adelaide and the XPT to Sydney are provided seperately to VLine services. Victoria’s GTFS feed is published by Public Transport Victoria (PTV)<sup>9</sup>.

The developed code has been separately tested using SA1- and LGA-level areas of interest, including hand verification of some example SA1 areas<sup>10</sup>.

For the results reported here output was obtained for SA1-level areas using GTFS files from August 2016 and 2021, running for just the day of the census in each year. The Australian Census is undertaken in early August every 5 years. GTFS feeds were therefore selected for the first week of August of each year, with code output produced for only the day of the census itself<sup>11</sup>. Minor corrections were made to the GTFS files to remove duplicate stop\_ids<sup>12</sup>.

The Australian Bureau of Statistics (ABS) provides a range of

<sup>8</sup> Greater Melbourne is the term used to describe the larger metropolitan area, encompassing 30 LGAs. The City of Melbourne LGA covers only a small portion of the inner city.

<sup>9</sup> There are over 400 historical releases of the available on the transitfeeds.com website, with the first dating from March 2015 [Transit Mobility Data., 2023].

<sup>10</sup> This testing is reported in the main branch of the project on GitHub. This document is instead specific to the calculation of the SI scores for the 2016 SA1 boundaries.

<sup>11</sup> It takes about a day of processing time to run the code for all of the stops in Victoria for a single ‘day’ of service. Hence, only the census days (rather than weeks) were analysed to speed development.

<sup>12</sup> These involved minor discrepancies in either the stop name, latitude or longitude.

shape files and other resources. This study made use of the `absmaps-data` R package [Mackey, 2023] to access the SA1 boundaries for Victoria used during the 2016 census (SA1\_2016)<sup>13</sup>. The EPSG:28355 transform [EPSG, 1995] was used to shift longitude and latitude into metres, as per the Geocentric Datum of Australia 1994 (GDA95 / MGA zone 55) coordinates.

The ABS provides IRSAD datasets for SA1 in excel format. Data for 2016 and 2021 was included in this study<sup>14</sup>.

ISRAD Scores for 2021 are shown in Figure 1 for the Melbourne City and Clayton case study areas.

<sup>13</sup> Note, there is also a set of SA1 boundaries that are relevant to the 2021 census (SA1\_2021).

<sup>14</sup> The IRSAD scores for 2021 appear to only be available for the SA12021 boundaries. A correspondance file was used to match the SA12021 to SA12016 boundaries, but it was not

Figure 1: 2021 IRSAD score for SA1s: within the Clayton SA2 zone (left) and within the Melbourne City SA3 zone (right)

The ISRAD scores appear to meet expectations. In Clayton there is no score reported for the Monash University campus, Likely due to its low resident population. Higher scores are reported for SA1s to the north-east of Clayton, in the Notting Hill area.

For the Melbourne City SA3 zone, there are no ISRAD scores reported for the various parks<sup>15</sup>. Areas with lower IRSAD scores are located in parts of North Melbourne and in the north-east<sup>16</sup>, which meets expectations.

<sup>15</sup> Royal Park to the north, Fitzroy Gardens and the sporting district to the east and south east, and the SA1 with the Docklands stadium in it.

<sup>16</sup> Lygon Street and Nicholson Street areas.

# Results

The following subsections discuss the results of running the code for all of Victoria for 2016 and 2021, and the looks in detail at the two selected cases (Clayton and Melbourne City) as a validation of the results.

## Supply Index results for all of Victoria

Four files are output by this document<sup>17</sup>. These include the total 2016 and 2021 SI scores for each SA12016 zone<sup>18</sup>, and the SI scores by mode<sup>19</sup>.

<sup>17</sup> Located in the ‘results’ subdirectory of the SA12016 branch in the github repository.

<sup>18</sup> Victoria\_2016\_SA\_SA2016\_160809.csv and Victoria\_2021\_SI\_SA12016\_210810.csv

<sup>19</sup> Victoria\_2016\_SI\_df\_by\_mode...etc.

## Verifying the code output

Code output results were verified by comparison to by-hand calculations for selected combinations of date and location in Victoria.

## Running Creek and Morgans Bridge, Kiwa Valley Hwy

The SA1 area 20403106915 covers Running Creek and Morgans Bridge, two localities in the Victorian Alps. Within this SA1 area there are only two V/Line bus stops<sup>20</sup>. This SA1 was selected for the purposes of verifying the code output as it is relatively easy to calculate the relevant SI values as a cross-check, because there is only one bus service and two stops to include. The location of the SA1 20403106915 is shown in the following figure. Relevant geographic statistics are shown in the following.

<sup>20</sup> Stop:ID 45125, Running Creek Rd/Kiwa Valley Hwy (Running Creek) and Stop ID: 45124, Kiwa Valley Hwy (Morgans Bridge).

Table 1: SA1 zone 20403106915

	sa1_code_2016	sa1_7dig_2016	sa2_code_2016	sa2_5dig_2016	sa2_name_2016	sa3_code_2016
20136	20403106915	2106915	204031069	21069	Bright - Mount Beauty	20403

The area of SA1 20403106915 is km<sup>2</sup>. By inspection, the entire 400m radius catchment area of both of the bus stops lie entirely within the SA1 20403106915 boundaries.

Hence the  $Area_{Bn}/Area_{SA1Area}$  term for each of the bus stops is equal to  $(\pi 400^2)/284598000 = 1.77e-03$ .

Figure 2: SA1 20403106915, with approximate location of Stop:ID 45125 highlighted, sources ABS and Google Maps

Anyhow, this concludes the hand-calculation verification efforts to date. The next sections, therefore, look at the code outputs alone, with a focus on LGAs in Greater Melbourne and Victoria.

The next sections show results for SA1 zones within Clayton and within Greater Melbourne, so as to provide some context for the results and as a cross-check.

### *SA1s within the Clayton SA2 zone*
